

# The Influence of Climate Variability on Internal Migration Flows in South Africa

Marina Mastrorillo, Rachel Licker, Pratikshya Bohra-Mishra,  
Giorgio Fagiolo, Lyndon Estes and Michael Oppenheimer

July, 6th 2016

FEEM Seminar

# Background

- Migration: One possible response to climate change
  - Internal vs international  
(Henry et al, 2003; Bohra-Mishra et al, 2014; Cai et al, 2014)
  - Rural to urban
  - Immobility (Gray and Mueller, 2012)
- Possible effects of climate on migration (Marchiori et al, 2012)
  - Direct: well-being, health
  - Indirect: agriculture, income, other economic channels
- Consequences on:
  - Migrants
  - Sending & receiving regions (Licker and Oppenheimer, 2013)

# Research questions

- 1 *Did climate variability influence internal migration flows in South Africa in recent history?*
- 2 *If so, is agriculture one of the possible channels through which adverse climate conditions enhance out-migration?*
- 3 *Does the effect of climate on migration vary by migrant characteristics?*

# Why South Africa?

- High internal migration rates

# Why South Africa?

- High internal migration rates
  - 2007-2011: 12% of SA population moved ( $\sim$  6m people)
  - 0.3% international, 11.7% internal, 5% across districts (StatsSA, 2011)

# Why South Africa?

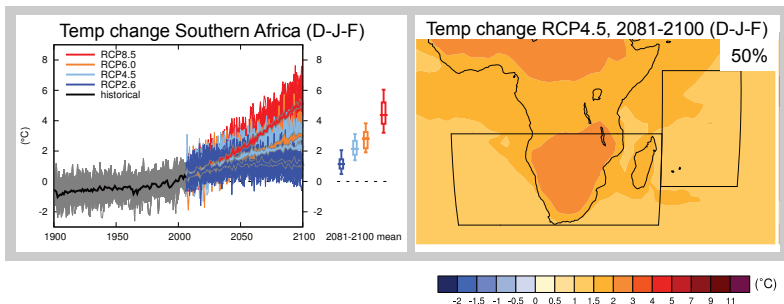

- High internal migration rates
- High inter-racial inequality and poverty ratio
  - Share of population below national poverty line: **53.8%** (in 2010)
  - Income Gini coefficient: **63.4%** (in 2011)

# Why South Africa?

- High internal migration rates
- High inter-racial inequality and poverty ratio
- Widespread and significant climate change projected

# Why South Africa?

- High internal migration rates
- High inter-racial inequality and poverty ratio
- Widespread and significant climate change projected

# Why South Africa?

- High internal migration rates
- High inter-racial inequality and poverty ratio
- Widespread and significant climate change projected

IPCC WGI AR5, 2013

# Why South Africa?

- High internal migration rates
- High inter-racial inequality and poverty ratio
- Widespread and significant climate change projected
- Relevance of agricultural sector

# Why South Africa?

- High internal migration rates
- High inter-racial inequality and poverty ratio
- Widespread and significant climate change projected
- Relevance of agricultural sector
  - 5-10% of formal employment; 20% of hh involved (2.9 m)
  - SA among top 10 world producers of maize and cereals
  - Large share of arid land, strong impact of climate change

# Why South Africa?

- High internal migration rates
- High inter-racial inequality and poverty ratio
- Widespread and significant climate change projected
- Relevance of agricultural sector
- No studies considering the effect of climate on migration in SA

# Data

- **Population Censuses**

- SA Census 1996, 2001, 2011; Community Survey 2007
- Information on : demographics, health, education, employment, households and services, **migration** (previous residence – year of move)

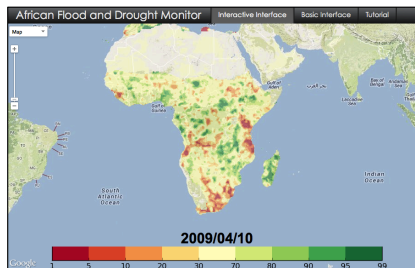

# Data

## • Population Censuses

- SA Census 1996, 2001, 2011; Community Survey 2007
- Information on : demographics, health, education, employment, households and services, **migration** (previous residence – year of move)

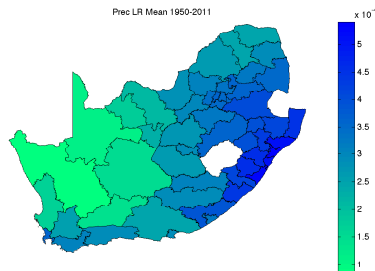

## • Climate Data

- Gridded data at 0.25 degree resolution
- Monthly, annual data on precipitation,  $T_{min}$ ,  $T_{max}$ , soil moisture (Sheffield et al, 2014)

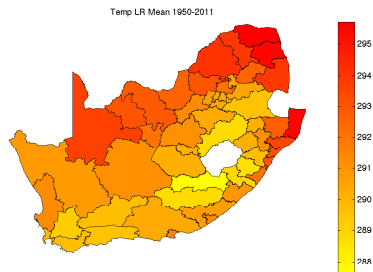

<http://hydrology.princeton.edu/monitor>

# Precipitation and temperature

- Long run average precipitation per km<sup>2</sup> (1950–2011)

- Long run average temperature in K degrees (1950–2011)

# Research design

- **Bilateral** (origin-destination) flows

# Research design

- **Bilateral** (origin-destination) flows
- **Inter-district** migration
  - 52 districts (either metropolitan or district municipalities)

# Research design

- **Bilateral** (origin-destination) flows
- **Inter-district** migration
- **Migrant**: an individual (15-64) who in year  $t = 2001, 2011$  was living in district  $j$  and moved there from district  $i \neq j$  within the 5 years before  $t$  (included)

# Research design

- **Bilateral** (origin-destination) flows
- **Inter-district** migration
- **Migrant**: an individual (15-64) who in year  $t = 2001, 2011$  was living in district  $j$  and moved there from district  $i \neq j$  within the 5 years before  $t$  (included)
- **Bilateral migration flows**: number of people (15-64) moving from district  $i$  ( $i = 1 \dots 52$ ) to district  $j \neq i$  during the 5 years before the Census year  $t$  (included)

# Characteristics of migrants: age

## % Migrants by Age

## % Migrants / % Population by Age

People among 15-64 years old cover 80% of migrants and are over-represented among migrants as compared to population

# Characteristics of migrants: ethnicity

## % Migrants by Ethnicity

## % Migrants/ % Pop by Ethnicity

Although black migrants are the majority, white migrants are largely over-represented as compared to population

# Characteristics of migrants: education

## % Migrants by Education

Highly educated migrants are the majority and are over-represented among migrants as compared to population

# Net migration rates 2007–2011

Net Migration Rate 2011

- In blue, Gauteng and Western Cape
- In orange and red, Limpopo and Eastern Cape

# Econometric framework: Gravity model

$$m_{ij}^t = \kappa \cdot \exp\{\varphi_i + \phi_j^t + \beta \mathbf{Z}_{ij} + \mu \mathbf{C}_i^{t-5,t} + \theta \mathbf{X}_i^\tau\} \cdot \varepsilon_{ij}^t$$

$i$  : origin district;  $j$  : destination district;  $t$  : 2001, 2011

$m_{ij}^t$  : bilateral migration flows

$\varphi_i, \phi_j^t$  : origin and time-destination fixed effects

$\mathbf{Z}_{ij}$  : bilateral variables (log of distance and contiguity dummy)

$\mathbf{C}_i^{t-5,t}$  : climate variables at origin (pos. max and neg. min temperature anomalies, pos. and neg. precipitation anomalies, soil moisture)

$\mathbf{X}_i^\tau$  : origin controls (e.g., population, ethnicity, education, unemployment rate);  $\tau = 1996, 2007$

Estimation technique: PPML vs OLS

# Determinants of migration flows

Variables	Sign
<b>Demographic :</b> <ul style="list-style-type: none"> <li>Population</li> <li>Share of white individuals</li> </ul>	+ +
<b>Geographic</b> (bilateral variables): <ul style="list-style-type: none"> <li>Origin-destination distance</li> <li>Contiguity</li> </ul>	- +
<b>Socio – economic :</b> <ul style="list-style-type: none"> <li>Unemployment rate</li> <li>Share of population with at most primary education</li> </ul>	+ -
<b>Climatic :</b> <ul style="list-style-type: none"> <li>Pos max temperature anomalies</li> <li>(Abs) neg min temperature anomalies</li> <li>Pos precipitation anomalies</li> <li>(Abs) neg precipitation anomalies</li> <li>Soil moisture</li> </ul>	+ <b>NS</b> + + -

# Main results

- **Results on climate are robust to:**
  - Alternative definition of migration flows (1 year flows)
  - Lagged climatic variables (92-96 for 2001 and 02-06 for 2011)
  - Alternative specifications of climatic variables
  - Alternative setups as to the way **push** and **pull** factors are modeled
    - Positive maximum temperature anomalies and soil moisture are not significant pull factors
    - Increase in rainfall anomalies at destination reduces migration towards those areas

# Conditioning flows to migrant characteristics

## Does climate affect unevenly South African migrants?

- By age (0-14; 15-30; 31-45; 46-64; 65+)
  - Inverse U-shaped relationship between age and the climate-migration coefficient
- By gender
  - No significant differences
- By marital status
  - No significant differences
- By ethnicity (black vs white)
  - Smaller impact on white migrants
- By income (below vs above median income)
  - Much smaller impact on richest migrants

# Interactions with agriculture

**Is the impact of climate on migration stronger in more agriculture-dependent districts?**

$$m_{ij}^t = \kappa \cdot \exp\{\psi_i + \phi_j^t + \beta \mathbf{Z}_{ij} + \theta \mathbf{X}_i^\tau + \mu \mathbf{C}_i^{t-5,t} + \alpha A_i^\tau + \gamma A_i^\tau \cdot \mathbf{C}_i^{t-5,t}\} \cdot \varepsilon_{ij}^t.$$

$A_i^\tau$ : Agriculture employment rate

# Interactions with agriculture

Is the impact of climate on migration stronger in more agriculture-dependent districts?

$$m_{ij}^t = \kappa \cdot \exp\{\psi_i + \phi_j^t + \beta \mathbf{Z}_{ij} + \theta \mathbf{X}_i^\tau + \mu \mathbf{C}_i^{t-5,t} + \alpha A_i^\tau + \gamma A_i^\tau \cdot \mathbf{C}_i^{t-5,t}\} \cdot \varepsilon_{ij}^t.$$

$A_i^\tau$ : Agriculture employment rate

- Increases in max temp anomalies and reduction in soil moisture enhance migration **more strongly** in agriculture-dependent districts (significant interaction terms)
- The relationship between employment in agriculture and the effect of precipitation on migration is less clearcut
- Positive effect of agriculture on migration (holding climate constant)

# Indirect effects

Is agriculture a channel through which climate impacts migration?

- 1 We regress the agricultural var  $A_i^T$  against climate

$$A_i^T = \kappa + \varphi_i + \zeta_\tau + \mu \mathbf{C}_i^{T*} + \epsilon_i^T$$

- $\uparrow$  pos temp anom /  $\uparrow$  prec anom /  $\downarrow$  soil moist  $\Rightarrow \downarrow A_i^T$

# Indirect effects

Is agriculture a channel through which climate impacts migration?

- 1 We regress the agricultural var  $A_i^\tau$  against climate

$$A_i^\tau = \kappa + \varphi_i + \zeta_\tau + \mu \mathbf{C}_i^{\tau*} + \epsilon_i^\tau$$

- $\uparrow$  pos temp anom /  $\uparrow$  prec anom /  $\downarrow$  soil moist  $\Rightarrow \downarrow A_i^\tau$

- 2 We regress migration against the predicted agricultural var  $\hat{A}_i^\tau$

$$m_{ij}^t = \kappa \cdot \exp\{\psi_i + \phi_j^t + \beta \mathbf{Z}_{ij} + \theta \mathbf{X}_i^\tau + \alpha \hat{A}_i^\tau\} \cdot \varepsilon_{ij}^t$$

- $\downarrow \hat{A}_i^\tau \Rightarrow \uparrow m_{ij}^t$

# Summing Up

- First study on climate as a determinant of internal migration in SA

# Summing Up

- First study on climate as a determinant of internal migration in SA
- Consistent impact of climate on migration

# Summing Up

- First study on climate as a determinant of internal migration in SA
- Consistent impact of climate on migration
- Strong impact of climate on black and low-income South African migrants; weak impact on white and high-income migrants

# Summing Up

- First study on climate as a determinant of internal migration in SA
- Consistent impact of climate on migration
- Strong impact of climate on black and low-income South African migrants; weak impact on white and high-income migrants
- The effect of temperature anomalies and soil moisture is stronger in more agriculture-dependent districts

# Summing Up

- First study on climate as a determinant of internal migration in SA
- Consistent impact of climate on migration
- Strong impact of climate on black and low-income South African migrants; weak impact on white and high-income migrants
- The effect of temperature anomalies and soil moisture is stronger in more agriculture-dependent districts
- Adverse climatic conditions seem to affect migration through agriculture

# Future work

- ① Providing consistent estimates of the climate/migration relationship at a global scale
  - Harmonization of definitions of migration, of socio-economic and demographic controls and of climatic variables
  - Identification of a family of micro- and macro-econometric models

# Future work

- ① Providing consistent estimates of the climate/migration relationship at a global scale
  - Harmonization of definitions of migration, of socio-economic and demographic controls and of climatic variables
  - Identification of a family of micro- and macro-econometric models
- ② Modeling migration behavior through an Agent-based Model (ABM)
  - Agents are provided with a utility function, a set of network linkages and some knowledge of opportunities in other areas
  - Decision is some bounded-rational expected utility maximization scheme
  - Income diversification and migration might compete as strategies

# THANK YOU!

# Climatic Variables

- **Positive maximum temperature anomalies:** Positive values of maximum temperature in the 5 years before the Census minus long-run mean divided by long-run standard deviation (long run = 1950-2011)
- **Positive precipitation anomalies in the rainy season:** Positive values of average precipitation in the 5 years before the Census (rainy season) minus long-run mean divided by long-run standard deviation
- **Negative precipitation anomalies in the rainy season:** Negative values of average precipitation in the 5 years before the Census (rainy season) minus long-run mean divided by long-run standard deviation
- **Soil Moisture:** Relative soil moisture of the top layer (0-10 cm) calculated from the land surface model output (average over the 5 years before the Census) – Sheffield et al. (2004)
