"The Capacity of Storage-Reservoirs for Water-Supply."

By W. RIPPL, Docent at the Royal Technical High School
at Gratz (Styria).

1. INTRODUCTION.

In the English system for the water-supply of towns, by collecting the drainage of large catchment-basins, one of the most important problems is the determination of the capacity for storage, which should be provided in the reservoirs.

In the earlier works designed on this plan this point did not receive sufficient attention, because at that time the data required were not available. Hence reservoirs were constructed of insufficient size, causing a sensible deficiency in the water-supply in dry seasons. As the dams of the storage-reservoirs could not be raised in height without endangering their stability, new reservoirs and new gathering-grounds had to be added—a proceeding sometimes difficult and always costly.

For a long time engineers were obliged to apply the results of experience gained in existing waterworks to the design of new systems, by giving to the reservoirs a fixed capacity for a given area of gathering-ground. If, for example, in an existing system of water-supply, a storage-capacity of 2,500 cubic metres (88,288 cubic feet) was found adequate for 1,000 hectares (2,471 acres) of gathering-ground, the reservoir of a new system was designed to afford a proportionate storage-capacity. But as the amount of storage necessary depends on circumstances which vary in different localities, it is clear that in reservoirs thus designed, it is only by accident that a deficiency of water-supply, in a series of years, is prevented.

2. THE ORDINARY FORMULA.

The purpose of the storage-reservoir is to equalise the fluctuations of supply and demand during an indefinitely long period of time. The circumstances of an average year are therefore not sufficient to determine the quantity to be stored. Hence empirical rule has been adduced, based on the conditions which

Dam operation design
is an optimal control problem

The problem: feedback control

The long-term optimal operation of water resource systems can be formulated as a ***q*-objective stochastic optimal control problem**

$$\min_{\mu_t(\cdot)} \mathbf{J} = |J^1 \ J^2 \dots J^q|$$

subject to

$$\mathbf{x}_{t+1} = f_t(\mathbf{x}_t, \mathbf{u}_t, \varepsilon_{t+1})$$

$$\mathbf{u}_t = \mu_t(\mathbf{x}_t)$$

$$\varepsilon_{t+1} \sim \phi(\cdot)$$

The classic solution: Stochastic Dynamic Programming

Richard Bellman

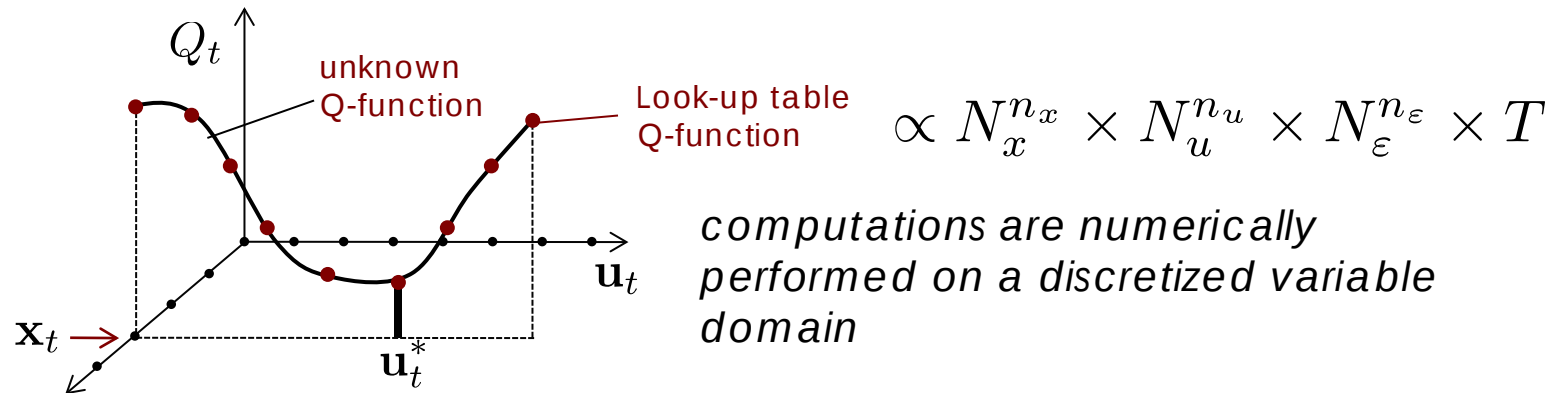

SDP provides an **optimal solution** under the following assumptions:

- 1) Discrete variable domain
- 2) Objectives and constraints must be time-separable
- 3) Disturbance process is time-independent

SDP and the 3 curses

In practice, SDP suffers from 3 major limitations

- 1) **Curse of dimensionality:** computational cost grows exponentially with state, control and disturbance dimension [Bellman, 1967];

SDP and the 3 curses

In practice, SDP suffers from 3 major limitations

- 1) **Curse of dimensionality:** computational cost grows exponentially with state, control and disturbance dimension [Bellman, 1967];

- 2) **Curse of modelling:** any variable considered among the operating rule's arguments has to be described by a dynamic model [Bertsekas and Tsitsiklis, 1996];

models are used in a multiple one-step-ahead-simulation mode

SDP and the 3 curses

In practice, SDP suffers from 3 major limitations

- 3) Curse of multiple objectives:** computational cost grows factorially with the number of objectives considered [Powell, 2011].

multi-objective problems are solved by reiteratively solving single objective problems (weighting method)

SDP and the 3 curses

In practice, SDP suffers from 3 major limitations

3) Curse of multiple objectives: computational cost grows factorially with the number of objectives considered [Powell, 2011].

Beyond SDP: ADP and RL

Approximate Dynamic Programming and Reinforcement Learning provide a framework to overcome some or all the SDP's curses.

[Powell, 2007; Busoniu et al. 2011]

VALUE FUNCTION-BASED APPROACHES:

- Approximate value iteration [Johnson et, 1993]
- Approximate policy iteration

Model-free or model-based // parametric or non-parametric

POLICY SEARCH-BASED APPROACHES:

- Direct policy search

Simulation-based optimization // parametric

ROLLING POLICIES

Conclusions

- MODPS framework is an interesting alternative to SDP family methods for a number of good reasons
 1. No discretization required: **NO curse of dimensionality**;
 2. Does not require separability in time of constraints and objective functions (e.g. duration curves): **NO curse of dimensionality**;
 3. Can easily include any model-free information as long as this is control-independent: **NO curse of modelling**;
 4. Can be combined with any simulation model (also high fidelity ones): **NO curse of modelling**;
 5. Can be easily combined with truly multi-objective optimization algorithms: **NO curse of the multiple objectives**.

M3O: a toolbox for reservoir operation design

The screenshot shows a web browser window with the address bar displaying 'mxgiuliani00.github.io'. The main heading is 'M3O: Multi-Objective Optimal Operations' in a large, bold, black font. Below the heading, a subtitle reads 'M3O is a Matlab toolbox for designing the optimal operations of multipurpose water reservoir systems'. Three buttons are visible: 'Download .zip', 'Download .tar.gz', and 'View on GitHub'. Below these buttons, a section titled 'M3O: Multi-Objective Optimal Operations' in red text is followed by a paragraph describing the toolbox. At the bottom, a section titled 'List of methods available' in red text is followed by a dark gray box containing a bulleted list of methods.

M3O: Multi-Objective Optimal Operations

M3O is a Matlab toolbox for designing the optimal operations of multipurpose water reservoir systems. M3O allows users to design Pareto optimal (or approximate) operating policies for managing water reservoir systems through several alternative state-of-the-art methods. Version 1.0 of M3O includes Deterministic and Stochastic Dynamic Programming, Implicit Stochastic Optimization, Sampling Stochastic Dynamic Programming, fitted Q-iteration, Evolutionary Multi-Objective Direct Policy Search, and Model Predictive Control. The toolbox is designed to be accessible to practitioners, researchers, and students, and to provide a fully commented and customizable code for more experienced users.

List of methods available

- Deterministic Dynamic Programming (DDP)
- Stochastic Dynamic Programming (SDP)
- Implicit Stochastic Optimization (ISO)
- Sampling Stochastic Dynamic Programming (SSDP)
- Evolutionary Multi-Objective Direct Policy Search (EMODPS)
- Fitted Q-Iteration (FQI)
- Model Predictive Control (MPC)

Survey on Weather and Climate Services for Hydropower

The IMPRES project (IMproving PRedictions and management of hydrological EXtremes) is a research project supported by the European Commission under the Horizon 2020 programme (<http://www.imprex.eu>).

IMPRES investigates the value of improving predictions of hydrometeorological extremes at short-, medium- and long-range in a number of water sectors, including hydropower.

The project's rationale is based on the fact that we can, and we should, learn from today's experience and practice to better anticipate the needs (and trigger the opportunities) of tomorrow.

With this particular survey, we aim to collect your viewpoint on the need for and the value of weather and climate services for the hydropower sector in Europe and internationally. The purpose is to help us to improve current forecast products and enhance their usefulness.

Filling in the questionnaire will only take about 10 minutes of your time but will be extremely valuable for the IMPRES project.

All answers will be treated confidentially and anonymously.

Thank you in advance,

The IMPRES WP8 group

CTI - Swiss Commission for Technology and Innovation
SCCER SoE

In Brief

The aim of the Swiss Competence Center for Energy Research is to provide a platform for the exchange of knowledge and expertise in the field of energy research and to support the development of new technologies and processes.

The SCCER SoE is a joint venture between the Swiss State Secretariat for Energy and Sustainable Development (SESD) and the Swiss Commission for Technology and Innovation (CTI). It is a non-profit organization that is dedicated to the advancement of energy research and the development of new technologies and processes.

The SCCER SoE is a platform for the exchange of knowledge and expertise in the field of energy research and to support the development of new technologies and processes. It is a non-profit organization that is dedicated to the advancement of energy research and the development of new technologies and processes.

Mission

The SCCER-SoE is compiling answers to the following questions:

- How can we ensure a secure and sustainable energy supply for the future?
- Is CO₂ capture and storage (CCS) a viable option for reducing greenhouse gas emissions?
- How can we improve the efficiency of energy conversion and distribution?

The SCCER SoE is a platform for the exchange of knowledge and expertise in the field of energy research and to support the development of new technologies and processes.
