SUMMARY

World agriculture is based on a small number of animal species and a decreasing number of breeds within each species. Several breeds of West African shorthorn cattle (*Bos taurus brachyceros*) are now at high risk of extinction due to interbreeding. The West African shorthorn breeds are particularly important resources because of their superior abilities to resist diseases, particularly trypanosomosis, and be productive under high humidity, heat stress, water restriction and with poor quality feed. An analysis of farmers' breeding practices and breed preferences in a sample area in southwest Nigeria confirmed a strong trend away from trypanotolerant breeds, especially Muturu, and identified the traits farmers find least desirable in these breeds relative to zebu (*Bos indicus*) breeds. An analysis of cattle market prices found that buyers have preferences for specific breeds for specific purposes and that though in general price differences due to breed are small, in some cases buyers pay significantly different prices for certain breeds consistent with their preferences. The best hopes for increased utilization of breeds at risk such as Muturu is likely in other areas of West Africa, for example in southeast Nigeria, where the Muturu is better suited to the farming systems and there is a large market for this breed to provide incentives.

Keywords: Cattle breeds, market prices, farmer preferences, genetic resources, conservation

NON TECHNICAL SUMMARY

An hedonic approach is used to analyse farmers' breeding practices and breed preferences in southwest Nigeria. They confirm a strong trend away from trypanotolerant breeds, especially Muturu, and identify the traits farmers find least desirable in these breeds relative to other zebu breeds. Results suggest that implementing a conservation/sustainable use strategy for breeds at risk such as Muturu is likely to be best in other areas of West Africa; for example in southeast Nigeria where trypanosomosis remains a constraint, where the Muturu is better suited to the farming systems and where a large market for this breed continues to exist.

Introduction

There is an increasing global concern about the potential long-term consequences of loss of plant and animal genetic diversity and the need to conserve genetic resources. The world's animal agriculture is dependent upon about 40 species of mammals and birds, each with a great pool of genetic diversity. With the spread of domesticated animal agriculture across the planet during the last 10,000 to 12,000 years, different species of animals adapted to a wide range of environmental conditions and developed specialised strains and traits, many of which have become extinct or are now in danger of extinction. It has been suggested that globally 618 breeds of domestic animals have already become extinct (Hall and Ruane, 1993) and in Europe one third of the surviving 737 distinct breeds of livestock are in danger of extinction (Cunningham, 1992).

A recent survey in sub-Saharan Africa revealed that out of 145 cattle breeds identified, 47 (32%) were considered to be at risk of extinction, and 22(13%) previously recognised in the continent have already become extinct (Rege, 1999). The sub-humid and humid zones of West and Central Africa, the primary focus of this paper, is the home of some of these extinct breeds and the breeds at risk of extinction. These breeds at risk have developed, over the centuries since their predecessors were introduced into West and Central Africa, the ability to survive and be productive in areas of high humidity, heat stress, water restriction and poor quality feed, and more importantly low to moderate trypanosomosis risk, hence are considered to be trypanotolerant. The *Bos taurus* breeds also reportedly have superior levels of resistance to other diseases e.g., streptothricosis, ticks and tick-borne diseases, helminthosis high humidity, heat stress, water restriction and poor quality feed (Murray et al., 1990; d'Ieteren, 1994; Rege, 1999). These superior adaptive abilities make these breeds valuable for further livestock development in West and Central Africa and other harsh environments around the world. Achieving this goal will require conservation and

improvement of the genetic resources carried by these breeds under risk.

The main threat of extinction for these breeds is interbreeding, especially with the humped *Bos indicus* breeds that have moved into the sub-humid and humid regions of West and Central Africa during the last 30 years. High population pressure and periodic droughts in the arid and semi-arid areas have prompted the owners of zebu cattle to extend their seasonal transhumance and relocate their permanent settlements further south. The rate of interbreeding depends upon the breeding strategies and breed preferences of the farmers on the one hand and preferences of consumers on the other.

The primary objectives of this paper are to improve understanding of cattle farmers' breeding practices and breed preferences and determine if buyers have systematic preferences for specific breeds of cattle for specific purposes and whether they pay significantly different prices for different breeds consistent with their preferences. *Ex ante* assessment of farmers' breeding strategies and breed preferences and market values of different breeds can assist breed conservation and improvement efforts in several ways. First, it can help to assess current stocks of different breeds held by farmers, the geographic distribution of these stocks, and the likely future trends in these stocks. Interbreeding is more likely among animals raised in close proximity and when different breeds are raised in the same herd. Second, farmers' knowledge about specific attributes of different breeds under village conditions can help to focus scientific research on particular traits and identify needs for further farmer education through extension programmes. Third, it can help to determine the incentives that may need to be put in place for farmers to be involved in the conservation of threatened or endangered breeds that may not be supported by market forces. Fourth, information about farmers' breeding practices and breed preferences can help to identify the likely market for existing or improved breeds, as market information reveals buyer preferences for different breeds and attributes can be useful in the design of breed improvement schemes.

In section 2, the study area, data sources and analytical methods are described. In section 3, results are presented and discussed. Implications of the findings and conclusions are presented at the end.

Data Source and Methodology

The study area

In West and Central Africa, in the mid-1970s about 7 million *Bos taurus* cattle, including the 4.8 million N'Dama and the 2.2 million West African shorthorns, were most numerous in the more humid southern region, the trypanosusceptible *Bos indicus* breeds were most numerous in the drier northern region covering the Sahel, and most of the three million cross-breed populations were found in the boundary area between the two regions (ILCA/FAO/UNEP, 1979). The present study focused on a boundary area because interbreeding and genetic introgression is most likely in those areas and farmers in those areas are more likely to have information about the advantages and disadvantages of different breeds and the option of bringing different breeds into their herds. The particular boundary area chosen for this study is in the derived savannah ecozone - a transition zone between humid and sub humid zones - of Oyo State, southwest Nigeria, where most of the cattle in southern Nigeria are located. Cattle breeds commonly found in southern Nigeria are: Muturu -- a trypanotolerant *Bos taurus* breed; White Fulani -- a trypanosusceptible *Bos indicus* breed; Keteku -- a stabilized cross between Muturu and White Fulani; and N'Dama -- a trypanotolerant *Bos Taurus* breed introduced into southern Nigeria through breed improvement programmes undertaken since the early 1970s.

As of 1959 there were about 65,000 cattle in southern Nigeria, most of which were Muturu and Keteku. Since that time the number of cattle in southern Nigeria has increased rapidly as

Fulbe pastoralists have moved large numbers of White Fulani cattle into the region. The cattle population increased to 100,000 in 1974/75, to 140,000 in 1984 and to 234,000 in 1990 (RIM, 1992; Blench, 1994). At the same time the number of trypanotolerant cattle in the region, particularly Muturu and Keteku, have decreased. The number of Muturu in all of Nigeria has decreased from about 200,000 in 1938 to between 60,000 - 115,000 in recent times (Hoste et al., 1992; Akinwumi and Ikpi, 1985; RIM, 1992).

Between 1980 and 1983, 5,000 N'Dama were imported from The Gambia to Nigeria as breeding stock. These were multiplied and disseminated from five government ranches in southern Nigeria. The total number of N'Dama in the country increased from 14,800 in 1975 to 24,800 in 1984 (ILCA/FAO/UNEP, 1979; Hoste et al., 1992). Although N'Dama are raised as multi-purpose animals in The Gambia, early adopters of the N'Dama in southern Nigeria raised them primarily for beef (Jabbar et al., 1995).

Household sample and data

A survey of cattle-holding households in the derived savanna ecozone of Oyo state was conducted between January and June 1994. Oyo state is divided into four administrative zones for agricultural extension purposes - Ibadan, Oyo, Ogbomosho and Shaki. Of these, Ibadan, which falls primarily in the forest zone, has a small number of Muturu cattle, but very few cattle of any other breed. The study therefore focused on the other three zones where a combination of breeds was known to be raised. Each zone is divided for administrative purposes into a number of block each containing 50-80 villages and 5,000-10,000 households. Based on information provided by the Ministry of Agriculture, from previous surveys and key informants, two blocks were selected from each of the three zones to represent the different agro climatic situations within the derived savannah ecozone of Oyo state.

In the 6 sample blocks there were 377 villages and 41,321 households of which 292 (less than 1%) were described as settled cattle farmers, i.e. farmers engaged in both livestock and crop production with a semi-permanent or permanent dwelling. All other households were principally crop farmers with some small ruminants but no cattle. Of the 292 households, 66 had cattle when they settled, but for a variety of reasons, had no cattle at the time of the survey. Individual interviews were conducted with the 226 households who held cattle at the time of the survey. Among them 210 belong to the Fulbe ethnic group who migrated from the north and 16 belong to the local Yoruba ethnic group.

Data were collected on settlement, breed and sex composition of cattle herds, and sources of cattle currently in the herd. Respondents were also asked open-ended questions about the main advantages and disadvantages of 5 breeds with which they might be familiar - White Fulani, Keteku, Muturu, N'Dama and crosses of White Fulani and N'Dama. Respondents were asked to rate, using a matrix rating approach, the 5 breeds according to a set of criteria that had emerged as most important from previous studies (e.g. Mohammed, 1990; Jabbar et al.,1995) and through key informant interviews with cattle farmers. The criteria were: milk yield, disease resistance, size of animal, ease of handling, market value, marketability (ease of finding buyers), ability to graze diverse species of grasses, need for moving long distances for grazing, and overall desirability. An animal with ability to graze diverse grasses would have less need for moving long distances for grazing but, to avoid disease infested areas, particularly that of trypanosomiasis, animals may have to be moved long distances. The meaning of each row, column and cell in the matrix was explained to each respondent during the household interview. Each breed could be rated between 1 (poorest or lowest or least preferred) and 10 (best or highest or most preferred) for each criterion, so the respondent was asked to consider the first criteria and put between one and 10 bean seeds in the cell corresponding to each breed. The respondent was then asked to consider the remaining 8

criteria in the same way. Of the 226 interviews that were conducted with sedentary cattle farmers, 204 (90 percent) produced complete data regarding breeding practices and breed preferences.

Logit analysis of breed preference rating

Preference rating is a response variable that can be considered as measured on an ordinal scale. The ordering shows the strength of preference for an item. The LOGISTIC procedure in SAS (SAS, 1995, 1999) can be used to fit a model with an ordinal response variable. This procedure fits a parallel lines regression model that is based on the cumulative distribution probabilities of the response categories.

In this study, the response has 10 possible outcomes: 1 = strongly dislike, ..., 10 = strongly like.

So we define:

$$P_i = \text{prob}(Y = i \mid X), \text{ for } i=1, \dots, 10;$$

where Y is the response variable and X is a continuous predictor variable.

PROC LOGISTIC in SAS fits the following model:

$$\text{logit}(p_1) = \log(p_1/(1-p_1)) = \alpha_1 + \beta * X$$

$$\text{logit}(p_1+p_2) = \log((p_1+p_2)/(1-p_1-p_2)) = \alpha_2 + \beta * X$$

.

.

PROC LOGISTIC models the cumulative probabilities assuming a common slope parameter associated with the predictor variable. The model is called the proportional-odds model, because the ratio of the odds of the event Y inferior or equal to j is independent of the category, j . This means that the odds ratio is constant for all categories.

In this analysis, the response levels are sorted in ascending order. The score chi-square is used to test the appropriateness of the proportional odds model. High p-value suggest adequacy of the model in fitting the data.

Market data

A rapid appraisal of cattle markets in southwest Nigeria was undertaken to characterize patterns of trade and breeds of animals transacted at each market. The Shaki market, located in the northwest of Oyo state, about 10 kilometres from the border between Nigeria and the Republic of Benin, was chosen for indepth study since the greatest variety of breeds were exchanged there. Data were collected for 2,688 cattle transactions conducted on 49 market days between November 1993 and June 1994. Data were collected more frequently when more animals were exchanged such as before festivals. All data were collected on Mondays, Wednesdays and Fridays. Five breeds of cattle were transacted during those 49 market days: Muturu, Keteku, N'Dama, White Fulani and Sokoto Gudali. The first three are trypanotolerant taurine breeds while the other two are trypanosusceptible zebu breeds. The rapid appraisal indicated that relatively few trypanotolerant cattle were exchanged compared to the trypanosusceptible breeds. In order to ensure adequate samples of all breeds, data were collected for all transactions involving N'Dama, Keteku and Muturu and a random sample of transactions involving White Fulani and Sokoto Gudali.

For each transaction, data were collected on price (Nigerian Naira per head) and various

factors hypothesized to affect price: attributes of the animal, attributes of the seller and the buyer. Since animals are not weighed at the Shaki market, a Bovine Weighing Tape (manufactured by WASCO, Fort Atkinson, Wisconsin, USA) was used to measure height at the withers, length and girth circumference following the procedure described by Buvanendran et al. (1980). The tape gives an estimated weight of the animal corresponding to its girth circumference. Also weight was estimated by using the following formula: live weight = (length x girth²)/300 (Payne, 1990). The two weight estimates were found to be highly correlated ($r = 0.97$).

Implicit price analysis

An implicit or hedonic price function was estimated to relate the price per animal to its various attributes and characteristics. The maintained hypothesis of implicit price analysis is that products have attributes that confer utility and that the values of those attributes contribute to the price of the product. The observed product price is therefore a composite of the implicit prices of the product's attributes (Rosen, 1974; Lucas, 1975). In this analysis the focus was on the importance of breed relative to other attributes likely to affect the price of cattle. The hypothesis that was tested was as follows: everything else equal, there were no differences in price per animal due solely to breed.

In a competitive market an implicit price will be a function of the product attributes alone, and not of individual consumer or supplier attributes (Rosen, 1974; Ockowski, 1994). This implies that only products are differentiated, while their markets, buyers and sellers are not. However, most empirical studies found that price was also related to attributes of the buyers and sellers, implying some non-competitiveness in the market (e.g. Brorsen et al., 1984; Francis, 1990; Andargachew and Brokken, 1993; Parker, 1993; Parker and Zilberman, 1993; Williams et al., 1993; Oczkowski, 1994; Rodriguez et al., 1995).

The general form of the implicit price function may be written as $P = F(Q,C) + e$

where P is the observed price of the product, Q is a set of qualitative (discrete) variables or factors each with more than one category, C is a set of quantitative variables (covariates), and e is an error term. Interaction variables may also be incorporated. The partial derivative of the estimated function with respect to a quantitative variable is the implicit marginal value of the attribute. Qualitative attributes are represented by dummy variables so the estimated parameters measure the impact of the presence or absence of the attribute. Therefore, the predicted price cannot be directly obtained from the partial derivatives, and hence additional manipulation would be required (Gujarati, 1988).

The SPSS Analysis of Covariance procedure (Norusis, 1993) was used to estimate the model parameters. Bonferroni confidence intervals were used in the hypothesis tests in order to reduce the likelihood of false rejection of null hypotheses. The advantage of this procedure compared to linear regression is that the results can be interpreted more directly and easily to compare differences between categories of a factor, as the estimated parameters indicate both the direction and absolute value of the differences from a base category. The factors and covariates used in the analysis are discussed later.

Results and Discussion

Farmers' present and past breeding practices

Among the 204 sample herds, 69% contained only White Fulani, 24% contained White Fulani and Keteku, 4% contained mixtures including White Fulani, Keteku and N'Dama, and 3% contained only Keteku. None of the herds contained Muturu. The 55 households that were caretakers of animals had been settled in their current location longer than other households (average of 40 years compared to 27 years) and were less likely to hold pure White Fulani herds (47% compared to 77%). Herd size and composition were fairly similar

among the groups.

Table 1 shows how the breed composition of the farmers' cattle holdings changed over time. Overall, there was a large shift away from the indigenous *Bos taurus* breeds, Muturu and Keteku, to White Fulani. Before the survey, 55% of the 204 households reared Muturu or Keteku, at the time of the survey 31% reared Keteku and none reared Muturu. While 44% of the households that had only White Fulani in the past had some Keteku at the time of the survey, 63% of the households that had only Muturu or Keteku in the past had only White Fulani at the time of the survey. Of the 113 farmers who gave reasons for giving up Muturu and/or Keteku, 75% mentioned poor market value, 66% mentioned low milk yield, 43% mentioned small size, and 27% mentioned wild temperament or difficulty in management or handling. Of the 43 farmers who gave reasons for adding trypanotolerant breeds to their herds, 51% mentioned disease resistance, 26% mentioned ability to graze a variety of grasses therefore less need for mobility, 14% mentioned better quality of milk, and 12% mentioned shorter calving interval.

Data on sources of cattle in the respondents' herds at the time of the survey are presented in Table 2. These data suggest that care-taking arrangements and interbreeding are the main ways that farmers exercise breed choice in their herds. Overall, 80% of the cattle held by the respondents were inherited or born to animals that were inherited, 14% originated through care-taking arrangements, and just 5% were purchased. Inheritance was the most important source for all breeds of cattle; care-taking was a much more important source for Keteku than for White Fulani.

Breed preference rating results

Table 3 shows the results of fitting the preference rating data to a logistic regression model.

The model is parameterized so that the Muturu, used as a reference breed, is assigned a parameter estimate of zero. All comparisons are made with respect to this breed. Since the strong dislike or least preferred ($Y=1$) end of the rating scale is associated with lower ordered values in the response profile distribution, the probability of disliking the breeds is modeled. The Chi-Square score test for testing the proportional odds assumption for milk yield rating is not significant with respect to a chi-squared distribution with 32 degrees of freedom ($p = .4339$). The proportional odds model assumption is therefore valid for milk yield rating. For other criteria, the p-values are very small because the probability distributions of ratings are more even rather than skewed as in the case of milk yield rating. The relative magnitudes of the parameter estimates with respect to each criterion imply the preference ordering as well as the distances between the breeds. Results in Table 3 shows that all the parameters are highly significant at $p\text{-value} = 0.05$, except in four cases where the outcome was not significant (ns in the table).

The results indicate that White Fulani is the most preferred breed and Keteku the second most preferred breed in terms of milk yield, size, ease of handling, market value, marketability, mobility needs while White Fulani is the least preferred breed and Keteku is second least preferred breed in terms of disease resistance and grazing diversity. N'Dama is the most preferred breed in terms of disease resistance and grazing diversity and the least or second least preferred breed in terms of milk yield, size, ease of handling, market value, marketability and mobility. Muturu is the second most preferred breed in terms of disease resistance and grazing diversity but least or second least preferred breed in terms of milk yield, size, ease of handling, market value, marketability and need for mobility. The White Fulani x N'Dama crosses lie somewhere in the middle.

The distances between the breeds in relation to a specific criterion can further qualify these orders of preferences. For example, White Fulani is the most preferred breed in terms of milk yield and its distance from the second best breed, Keteku, is very large. Also White Fulani is the least preferred breed in terms of disease resistance and its distance from the second least preferred breed, Keteku, is also very large. On the other hand, N'Dama is the most preferred breed in terms of disease resistance and its distance from the next best breed, Muturu, is not statistically significant. In the case of marketability, there is an order of preference but the distances between the breeds are less pronounced compared to other criteria. Based on all the criteria, the order of preference is as follows: White Fulani, Keteku, White Fulani x N'Dama, Muturu, and N'Dama.

Results of market and price analysis

There are significant differences between breeds purchased by different buyer categories. Traders purchased 62% of the Muturu and 56% of the Keteku. Sixty-six percent of all cattle traded were males, 29% were cows and 5% were heifers. Sixty-nine per cent of the traded animals were sold by traders and 31% were sold by farmers. Of the traded animals, 51% were purchased by traders for resale mainly in Eastern Nigeria, Lagos, Ibadan and in the local market, 23% were purchased by butchers and catering restaurants; 14% were purchased by consumers for various ceremonies and festivals, and 11% by farmers for rearing. Traders mostly purchased males (86%), while butchers mostly purchased females (77%). Farmer purchases included 7% cows, 32% heifers, 23% young males and 38% bulls, all of these mainly for rearing.

In the absence of weighing facilities in the market, because of their regular engagements in the market, traders and butchers have developed more experience and skill than other types of

buyers and sellers in evaluating the product quality attributes of each animal, the true value and the value a buyer or seller may put on it. This skill and knowledge primarily influence the margin they are able to derive from each transaction.

In the overall implicit price model run with the entire sample of traded animals, buyer type or purpose of buying was used as a factor along with other factors and covariates. In order to test whether differences in breed preferences for specific purposes were also reflected in price differences, interaction terms between purpose of buying and breed and type of animal were introduced. But because not all breeds were purchased for all purposes, or in some cases very few animals were purchased for a specific purpose, several cells in the data matrix were empty. In such cases, the model estimates the coefficients of the interaction terms assuming those empty cells as null or zero values but the hypothesis being tested in this way was not the hypothesis of interest in this study (see Norusis, 1993, for an explanation of the implications of estimating parameters assuming zero or empty cells). Therefore, rather than introducing interaction terms in the overall model, separate models were fitted to animals purchased for specific purposes, using relevant factors and categories.

Table 4 reports the results of the two best fit implicit price models, based on overall explanatory power, that were fitted to the entire sample. The difference between the two models is the exclusion of weight and weight square as covariates in model 1, so that the parameters of model 1 are not adjusted for differences in weight (a proxy for size) of the animals. The matrix rating from farm survey revealed that size is an important inherent characteristic of the various breeds – White Fulani and Gudali are larger compared to the other breeds. Therefore any significant price difference between breeds unadjusted for size may indicate that breed *per se* is valued by buyers (personal communication, Professor Robert Mendelshon, Yale University, 2000). The results, however, indicate that holding everything else equal, except size, there is no significant price difference between White Fulani and

Gudali, but the prices of all three trypanotolerant breeds are significantly lower than White Fulani and Gudali. When size is adjusted in model 2, no significant price difference exists between White Fulani, Gudali and N'Dama, but the prices of Keteku and Muturu are significantly lower, albeit with a much reduced magnitude. However, model 1 explains only 46% of total variation in prices compared to 72% in model 2 indicating that buyers consider both breed and size in valuing an animal. The significant negative effect of weight square in model 2 indicates that overall less premium is paid for heavier animals while the significant positive effect of condition score square indicates that higher premium is paid for animals in good condition.

Other significant results are that : (a) cows fetched significantly lower prices than males, while heifers fetched significantly higher prices than males; (b) traders paid significantly higher prices than either farmers or butchers/caterers/consumers (treatment of butchers, caterers and consumers as separate categories showed no significant difference between them hence they were combined); and (c) the highest prices were paid in December and lowest in January- March period.

Results of the purpose or buyer type specific models presented in Table 5 show that the explanatory power varies from 68% for animals purchased by farmers, to 79% for animals purchased by traders and 62% for animals purchased by butchers/caterers/consumers. Farmers did not pay significantly different prices for different breeds, but they paid significantly higher prices for cows and heifers compared to males, as they purchased animals mainly for rearing/breeding. Condition of animals did not significantly influence price paid by farmers, perhaps because if other desirable characteristics were present, the condition of the animal could be improved through rearing and appropriate management. Traders paid significantly lower prices for Muturu and Keteku compared to the other three breeds, also paid significantly

lower prices for cows (these are generally culled old cows having poor meat quality, hence the lower price), paid premium prices for animals in good condition and less premium for larger animals. Butchers/caterers/consumers paid significantly lower prices for Keteku compared to the other breeds, also paid lower prices for cows, and paid higher prices for larger animals as well animals in good condition.

Conclusions and Implications of Findings

Farmers in the derived savannah zone of Oyo State make deliberate choices about breeds of cattle in their herds based on specific criteria. They acquire breeds of choice principally through inheritance and breeding within own herds as well as through purchase and care-taking of other farmers' cattle. About 75% of the respondents reported that the breed composition of their herd was different at the time of the survey than it was in the past. There is a strong trend away from the *Bos taurus* Muturu and Keteku toward the *Bos indicus* White Fulani. Keteku was developed by interbreeding in the past by farmers as a deliberate choice to combine the disease resistance of Muturu and the larger size and milk yield of White Fulani. However, the decreasing number of Keteku at present indicates that as Muturu have disappeared from farmers' herds, so too may the Keteku. Although farmers acknowledged some clear advantages of the Muturu and Keteku (disease resistance, ability to graze a variety of grasses), those advantages appear to be of relatively little importance compared to the many disadvantages of the Muturu and Keteku relative to the White Fulani. Moreover, where disease challenge particularly that of trypanosomosis is smaller, there is less incentive to choose Muturu and Keteku against White Fulani.

The movement away from Muturu in the derived savannah areas of Oyo State is consistent with the aggregate trend in southwestern Nigeria. The national livestock survey conducted in

the early 1990s (RIM, 1992) found virtually no Muturu in Ogun State where not long ago many farmers held the breed (Grandin, 1980). The national livestock survey reported 11,623 Muturu among a total of 234,461 cattle in Oyo State (now Oyo and Osun states), but most of those Muturu were located in the forested areas.

The results of market price analysis show that there are some differences in prices that are solely due to breed, but that most variation in prices is due to size and condition of the animals. Generally, other things being equal, trypanotolerant breeds (Keteku, Muturu and N'Dama) commanded significantly lower prices compared to the larger trypanosusceptible breeds (White Fulani and Gudali). Although N'Dama prices generally appeared slightly higher than other breeds, in no case was the difference statistically significant. In an earlier analysis, girth and girth square rather than weight and weight square were used as covariates, and N'Dama prices in that case were found significantly higher than other breeds (See, Jabbar et al., 1998). However, purpose-specific equations run in this paper but not in the earlier case, show that overall, N'Dama has a slight edge, but not a significant one, in the market among all categories of buyers. But the total number of N'Dama in the sample is smaller in relation to the other breeds so this result should be treated with caution. However, this outcome is consistent with farm survey results, which show that farmers rated N'Dama low in terms of milk yield, ease of handling, market value and marketability. Though they rated N'Dama high in terms of disease resistance and grazing diversity. This partly explains why N'Dama population in the study area as well as in the rest of Nigeria did not expand as rapidly as would be expected after initial introduction by the government-funded project.

The strong trend among farmers against the trypanotolerant breeds especially Muturu implies that there is very little scope for conservation of the Muturu through continued farmer rearing in the derived savannah areas of southern Nigeria. If trends from the study area expand into the forested part of Oyo State, the population of 11,000 Muturu that is now reported could be

lost in a few years through interbreeding or outright exclusion from herds. This would mean the loss of an important resource for Nigeria and all regions of the world where livestock are raised under the stresses of disease, heat and humidity. The ability to be productive under low to moderate levels of trypanosomosis makes these animals more attractive to farmers. Trypanosomosis remains a constraint in southern Nigeria¹ and especially as there is evidence from across Africa of resistance to the drugs available for prophylactic and curative treatment of trypanosomosis (Peregrine et al., 1994).

Research and development agencies should consider the possibility of selecting Muturu bulls with superior production characteristics and promoting them with farmers who now keep Muturu in the forest zone. Conservation efforts might be better directed at locations, such as southeast Nigeria, where the Muturu is better suited to the farming system and where there is a distinct market for Muturu.

Note

¹ In 1987, in a sample of 1525 zebu cattle in 5 states of southwest Nigeria, a mean rate of trypanosome prevalence of 14.4% was found - 18% in the wet and 10.8% in the dry season (Ikede et al., 1987). A repeat survey in slightly wetter and more forested locations in 3 of the same 5 States showed prevalence rates of between 18.5% - 21% in the wet season and 16% in the dry season (ILRI-Ibadan, unpublished data).

For coefficients of covariates ***,** and * indicate t significant respectively at $p < 1\%$, 5% and 10% . For coefficient of the factor categories, * indicate the coefficient is significantly different from 0 i.e. the base category within the factor. Here significance is based on 0.95 Bonferroni confidence interval because when joint confidence intervals are constructed, t values are inadequate to determine whether differences are significant (Norusi, 1993).

SUBSCRIPTION TO "NOTE DI LAVORO"

Starting from January 1998 Fondazione Eni Enrico Mattei issues a Periodic E-mail "Note di Lavoro" Bulletin listing the titles and the abstracts of its most recent Working Papers.

All the "Note di Lavoro" listed in the Bulletin are available on the Internet and are downloadable from Feem's web site "www.feem.it".

If you wish to receive hard copies you may choose from the payment options listed in the following table (minimum order: 10 papers)*.

*Orders for individual papers should clearly indicate the "Nota di Lavoro" number and can therefore be issued for published papers only.

All orders must be sent by fax to:

"Publications Office" - Fondazione Eni Enrico Mattei: Fax +39+2+52036946
